

Devin Chapman

Part II: Coming Up With Ideas

1. I think Simplify and Me Too apply to Shyp. I think Simplify applies here because Shyp takes care of determining the optimal way to ship the product, and the user just has to specify a time and place and drop it off. I think Me Too applies here because there are similar websites like Ebay and Amazon, but since those websites make users ship the products they sell themselves, Shyp can target a different customer base who are unfamiliar with that process or are unable to ship it themselves.
2. I think Me Too and Remix apply to Curofy. Me Too applies here because Curofy is for the Indian market and based on LinkedIn. Remix also applies here because Curofy is based on LinkedIn, but Curofy is exclusively for doctors and offers features to be used by doctors such as discussing cases and staying informed on recent medical news.
3. I found the startup [Devin Voice](#) which is a realtime voice AI that allows a user to talk to a GPT-based AI agent simulating natural conversation and has it plan, code, and ship work. Simplify applies to this project because they are simplifying the agentic workflow by allowing the user to talk orally instead of typing, and Remix also applies because it combines spoken AI chatbots with coding-focused AI agents. Although most AI products tend to address the user's need to ship a product, I actually think Devin Voice more so targets the user's emotions, because there are already plenty of AI coding agents, so this product appeals to people who do not want to type or use the CLI and find it easier to talk orally. I'd say that this product is easy to monetize as many other AI agents run a subscription service model, and it is certainly an easy product to explain: it is simply an AI coding agent that works with oral speech rather than typing instructions. As someone studying computer science and dipping their toes into an agentic workflow this is personally relevant to me, although I generally prefer typing in the CLI and have never personally felt a need to switch over to a speech based agent. However, this product would probably be very useful to

those with less of a coding background, as well as disabled people who struggle to or are unable to type on a keyboard. This product probably does have a large market, as more people from non tech backgrounds are trying to ship products with AI, and this could streamline that process. This gear towards non tech-focused users could be the product's "secret sauce".

Part III: Finding Your Product

A. Brainstorming

1. In language learning circles there is a flashcard app called [Anki](#) which uses a "Spaced Repetition System" which spaces out cards over increasingly long intervals of time to integrate them into your memory. Essentially, if you see a new flashcard and get it right, you won't see it again for another 3 days, then another week, another 2.5 weeks, another month, and so on, repeatedly seeing the same word many times over a long period of time to truly remember it. Many people find words by watching YouTube or reading books or articles, and when they come across a new word that they don't know, they will make a card including the original sentence they found the word in and feed it to Anki. This is a great system with one fatal flaw: the users are seeing the same sentence several times, and often the user will read the first few words of their sentence and remember the sentence itself, but when they see the word again in a different context they struggle to remember because they only studied it from that single sentence.
2. Since so many users are making their own cards, despite everyone studying the single card they made for every word, there are probably dozens of cards made for most words in many languages if you were to combine everyone's deck. Knowing this, why not make a service that aggregates everyone's cards, checks the word a user wants to study, and feeds them a random sentence from the pool? This would keep all the benefits of Anki's spaced repetition system while also forcing the user to see a new sentence each time, and see the word in a new context instead of memorizing one sentence.

3. This was my only idea, and I've been playing with the idea of making a website like this for a month or so now. As someone who studies Japanese and finds myself struggling with the problem I described, I think many people could benefit from a product like this.
4. There is one similar website called [Immersion Kit](#) which allows users to upload and download Anki cards and to search for specific words, but it doesn't feed the user dynamic sentences like I want to. Immersion Kit is targeted as a website for people who find a word and want to make a flashcard of it in a different context that they may find easier to remember. Once a user downloads the card from Immersion Kit, they study that one card with the one sentence it contains. I want to take this idea and build on it, either integrating directly with Anki or making my own custom spaced repetition system so I can feed users a new sentence from the pool every time.
5. This product would not target an industry as much as it would target individuals who are interested in language learning.

B. Product Proposal

1. My product would combine a spaced repetition system like Anki with a card aggregation system like ImmersionKit to dynamically feed users a different sentence for each target word every time they see a flashcard. Remix applies to this project, because it takes ideas from Anki and Immersion Kit.
2. As someone who studies Japanese using Anki for my vocabulary this is personally very relevant to me.
3. My product would solve the problem of users seeing the same sentence for every vocabulary word every time they see it, causing users to subconsciously memorize the first few words of the sentence or the overall shape of the sentence and link it to a word, rather than fully understanding the word in context. Since [many words have several different unique meanings](#), just memorizing one sentence is usually not enough to understand the whole meaning of a word, and only memorizing the first few words or overall shape of a sentence instead of the word itself also decreases understanding a lot.

4. My website would be a self-contained business, as I could operate the card library like Immersion Kit and the spaced repetition system like Anki all in one place.
5. This product addresses the user's needs as it would be a better and more efficient way to study vocabulary.
6. I think my project would be easy to monetize with a subscription model.
7. For someone outside of the language learning space this is somewhat complicated to explain, but for someone familiar with spaced repetition systems, I think simply describing it as "A version of Anki that serves a new sentence each time you see a card" would get across very easily.
8. The users of my product would be anyone self-studying a language. Although this is a relatively small community, there are several products in the language learning space using a similar subscription model that are doing well, such as [Migaku](#).
9. I think my product does have a secret sauce, as it solves a problem that many people in the language learning community have.
